Rarebooksclub.com, United States, 2012. Paperback. Book Condition: New. 246 x 189 mm. Language: English . Brand New Book \*\*\*\*\* Print on Demand \*\*\*\*\*.This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. Excerpt: .it is not possible to resolve many lunar and planetary problems without carefully collected and documented samples and subsequent isotopic, chemical, and petrologic analyses. Five general extrapolations will be discussed: 1. Duration of volcanic activity on the Moon. 2. Early cratering history of the Moon before 3.84 b.y. ago. 3. Lunar multiringed basins and the provenance of lunar highland samples. 4. Regional and local chemical variations. 5. Variation of physical properties and roughness of lunar surface. DURATION OF VOLCANIC ACTIVITY Remote sensing and measurements indicate that volcanic flows continued to form well beyond the time indicated by samples returned by the Apollo and Luna missions. There are four lines of evidence for this. First, relative ages of the Imbrium flows and Oceanus Procellarum maria are younger than the mare of Apollo 12, where basalts are as young as 3.15 b.y. The best estimate from relative age determinations indicate that basalt continued to flow at least as recently as 2.5 b.y. ago. Second, the remarkable geographic coincidence between mare surfaces with young relative ages and mare surfaces with high infrared eclipse temperatures lends strong support to the youth of the Imbrium flows and maria in Oceanus Procellarum. High infrared eclipse temperatures indicate that the regoliths of these areas are blocky and relatively coarse grained. Such a result is consistent with relatively young volcanic flows overlain by relatively thin and immature regolith. Third, stratigraphic evidence for the youth of the Imbrium flows and some of the maria in Oceanus...
